Designation: D2532 – 22

Standard Test Method for Viscosity and Viscosity Change After Standing at Low Temperature of Aircraft Turbine Lubricants[1]

This standard is issued under the fixed designation D2532; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the U.S. Department of Defense.

1. Scope*

1.1 This test method covers the determination of the kinematic viscosity of aircraft turbine lubricants at low temperature, and the percent change of viscosity after a 3 h and a 72 h standing period at low temperature.

1.1.1 The range of kinematic viscosities covered by this test method is from 7700 mm^2/s to 14 000 mm^2/s at –40 °C and from 7000 mm^2/s to 17 500 mm^2/s at –51 °C. The precision has only been determined for those materials, kinematic viscosity ranges, and temperatures as shown in the precision section. Kinematic viscosities and percent change of viscosity may be measured and reported at other temperatures and other thermal soak period intervals as agreed by the contracting parties.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.2.1 The SI unit used in this test method for Kinematic Viscosity is mm^2/s. For user reference, 1 $mm^2/s = 10^{-6}$ m^2/s = 1 cSt.

1.3 **Warning—**Mercury has been designated by many regulatory agencies as a hazardous substance that can cause serious medical issues. Mercury, or its vapor, has been demonstrated to be hazardous to health and corrosive to materials. Use caution when handling mercury and mercury-containing products. See the applicable product Safety Data Sheet (SDS) for additional information. The potential exists that selling mercury or mercury-containing products, or both, is prohibited by local or national law. Users must determine legality of sales in their location.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety, health, and environmental practices and determine the applicability of regulatory limitations prior to use.* For specific hazard statements, see Section 7.

1.5 *This international standard was developed in accordance with internationally recognized principles on standardization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.*

3. Terminology

3.1 *Definitions:*

3.1.1 For definitions of terms used in this test method, refer to Terminology D4175.

3.1.2 *digital contact thermometer (DCT), n*—an electronic device consisting of a digital display and associated temperature sensing probe.

3.1.2.1 *Discussion*—This device consists of a temperature sensor connected to a measuring instrument; this instrument measures the temperature-dependent quantity of the sensor, computes the temperature from the measured quantity, and provides a digital output. This digital output goes to a digital display and/or recording device that may be internal or external to the device. These devices are sometimes referred to as "digital thermometers."

3.1.2.2 *Discussion*—PET is an acronym for portable electronic thermometers, a subset of digital contact thermometers (DCT).

4. Summary of Test Method

4.1 Kinematic viscosity and percent change is determined at low temperature using apparatus defined in Test Method D445 and Specifications D446 at time intervals of 3 h and 72 h following an initial measurement at 35 min.

5. Significance and Use

5.1 Aircraft turbine lubricants, upon standing at low temperatures for prolonged periods of time, may show an increase in kinematic viscosity. This increase may cause lubrication problems in aircraft engines. Thus, this test method is used to ensure that the kinematic viscosity does not exceed the maximum kinematic viscosity in certain specifications for aircraft turbine lubricants.

6. Apparatus

6.1 Viscometers, drying tubes, low-temperature bath, thermometer, timer, secondary viscosity standard, filter, and cleaning supplies are described in detail in Test Method D445.

6.2 *Viscometer*—The viscometer shall meet the requirements of Test Method D445 and Specifications D446 and be of the type in which the sample can be rerun without cleaning the viscometer. Suitable holders should be used. For convenience it is recommended that the viscometer size be chosen to keep the efflux time between 200 s and 1000 s.

NOTE 1—Consult Specifications D446 regarding calibration constant correction for the actual test temperature when using Specifications D446 viscometers that are not suspended level types.

6.3 *Drying Tubes*—Fit the viscometer openings with drying tubes filled with indicating silica gel, using cotton at top and bottom to hold the loosely packed desiccant in place. Provide a cross-connection on the viscometer side of the drying tubes (which can be closed by a pinch clamp or stopcock while liquid is being drawn into the efflux bulb) so that the restriction to air flow will not cause error. Replace the silica gel when a lavender color is noticeable.

6.4 *Viscosity Temperature Bath*—The constant-temperature bath must be capable of holding several viscometers at once. It must have adequate stirring of the liquid medium (Note 2) and balance between heat losses such that the bath temperature can be maintained at the required temperature ±0.03 °C.

NOTE 2—Isopropanol or other clear, low-freezing point liquid may be used as a bath liquid.

6.5 *Temperature Measuring Device*—Use either a digital contact thermometer as described in 6.5.2 with equal or better accuracy or a calibrated ASTM Kinematic Viscosity Test Thermometer such as 73C (–40 °C) or 74C or 43C (–51 °C) conforming to the requirements as prescribed in Specification E1 which have an accuracy after correction of ±0.03 °C or better. The ASTM 74C thermometer has a specification between –55.4 °C and –52.6 °C but is available from some suppliers with the scale expanded to cover –51 °C. The 43C thermometer is only graduated in 0.1 °C increments so interpretation at midpoints between the lines may be required.

6.5.1 When using liquid-in-glass thermometers, use a magnifying device to read the thermometer to the nearest ⅕ division (for example, 0.02 °C on thermometers graduated in 0.1 °C increments) to ensure that the required test temperature and temperature control capabilities are met.

6.5.1.1 Check the thermometer's ice point at least annually using an ice bath or a constant temperature bath against a reference thermometer. If the corrected temperature reading error is greater than the temperature tolerance, then the thermometer must be recalibrated.

6.5.2 When using a digital contact thermometer (DCT), the following requirements shall apply:

Criteria	Minimum Requirements
DCT	E2877 Class A
Display resolution	0.01 °C, recommended 0.001 °C
Display accuracy	±30 mK (±0.03 °C) for combined probe and sensor
Sensor type	RTD, such as a PRT or thermistor
Drift	less than 10 mK (0.01 °C) per year
Response time	less than or equal to 6 s as defined in Specification E1137
Linearity	10 mK over range of intended use
Calibration Report	The DCT shall have a report of temperature calibration traceable to a national calibration or metrology standards body issued by a competent calibration laboratory with demonstrated competency in temperature calibration. An ISO 17025 accredited laboratory with temperature calibration in its accreditation scope would meet this requirement.
Calibration Data	The calibration report shall include at least 3 calibration temperatures at least 5 °C apart which are appropriate for its intended use.
