

Designation: F3423/F3423M – 22

Standard Specification for Vertiport Design¹

This standard is issued under the fixed designation F3423/F3423M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification defines the requirements for the planning, design, and establishment of vertiports intended to service vertical takeoff and landing (VTOL) aircraft. These aircraft include, but are not limited to, standard category aircraft, optionally piloted aircraft, and unmanned aircraft. Aircraft not covered by this specification include VTOL aircraft less than 55 lb [25 kg]. In developing these standards, identified types of eVTOL aircraft, for example, Multi-Rotor, Lift & Cruise, Vectored Thrust, Tilt Wing, Tilt Rotor, etc., were considered. Ultimately it is up to the authorities having jurisdiction (AHJ) as to how and to what extent these standards are applied. Vertiports may provide commercial or private services in support of the operation of eVTOL aircraft including, but not limited to, some or all of occupant and cargo transport, air medical, flight instruction, aerial work, aircraft rental, fueling, charging of energy storage devices, battery exchange, hangaring, and maintenance services.

1.2 This specification is intended to support the design of civil vertiports and vertistops, however, it may also be used as a best practice document for other facilities.

1.2.1 *Vertiport* is a generic reference to the area of land, water, or structure used, or intended to be used, for the landing and takeoff of VTOL aircraft, together with associated buildings and facilities. At this time, aircraft with floats conducting water landings and takeoffs are not included in this specification.

1.2.2 *Vertistop*—The same as *Vertiport*, except that no fueling, defueling, scheduled maintenance, scheduled repairs, or storage of aircraft is permitted. Unscheduled maintenance and repairs to return an aircraft in an AOG (Aircraft on Ground) status to a serviceable status are permissible.

1.3 This document may present information in either SI units, English Engineering units, or both. The values stated in each system are not necessarily exact equivalents; therefore, to ensure conformance with the standard, each system shall be used independently of the other, and values from the two systems shall not be combined

¹ This specification is under the jurisdiction of ASTM Committee F38 on Unmanned Aircraft Systems and is the direct responsibility of Subcommittee F38.02 on Flight Operations.

Current edition approved July 1, 2022. Published August 2022. DOI: 10.1520/F3423_F3423M-22.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety, health, and environmental practices and determine the applicability of regulatory limitations prior to use.*

1.5 *This international standard was developed in accordance with internationally recognized principles on standardization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.*

3. Terminology

3.1 *Unique and Common Terminology*—Terminology used in multiple standards is defined in **F3341/F3341M**, UAS Terminology Standard, and **F3060**, Aircraft Terminology Standard. Terminology that is unique to this specification is defined in this section.

3.2 Definitions:

3.2.1 *Air Gap, n*—An unobstructed clear area dimensionally dependent on site-specific conditions that is located under a rooftop vertiport and between it and the architectural structure immediately below it, which is designed to allow the air circulating around and over a building to flow under the vertiport rather than over the vertiport to reduce turbulence at the landing and takeoff site(s).

3.2.2 *Air Taxi, n*—Used to describe a VTOL aircraft movement conducted above the surface but typically below 100 ft [30.5 m] AGL, which allows for more rapid aircraft movement from one point to another.

3.2.3 *Approach Surface (VFR), n*—The approach surface begins at each edge of the vertiport FATO with the same width as the FATO and extends outward and upward for a horizontal distance of 4000 ft [1219.2 m] where its width is then 500 ft [152.4 m]. The slope of the approach surface is 8:1. Although VTOL approach/departure paths may curve, the length of the approach/departure surface remains fixed. The approach surface slope may be reevaluated on a case-by-case basis at such time performance data for individual aircraft has been certified and published that would indicate a steeper, higher performance profile may be safely accomplished and accommodated for.

3.2.4 *Controlling Dimension (CD), n*—The greatest distance between the two outermost opposite points on an aircraft as measured along either the horizontal or longitudinal axis (that is, wingtip to wingtip, rotor tip to rotor tip, rotor tip to wingtip, fuselage to rotor tip, fuselage to fuselage, etc.), measured on a level horizontal plane that includes all adjustable components extended to their maximum outboard deflection. This equates to the smallest circle enclosing the VTOL aircraft projection on a horizontal plane in all possible operational configurations with rotor(s) turning.

3.2.5 *Design Aircraft, n*—A single or composite, that is, multiple, aircraft that reflects the maximum weight, maximum contact load/minimum contact area, controlling dimension, undercarriage dimensions, and pilot's eye height of all aircraft expected to operate at the vertiport.

3.2.6 *Dynamic Load, n*—For design purposes, assume the dynamic load at 150 percent of the maximum takeoff weight of the design aircraft applied through the main undercarriage on a wheel-equipped aircraft or aft contact areas of skid-equipped aircraft.

3.2.7 *Elevated Vertiport, n*—A vertiport located on a raised structure on land. (A ground-level vertiport where the TLOF is located on an earthen mound is not considered an elevated vertiport).

3.2.8 *Electric Vehicle Power Transfer System, n*—A means of replenishing an aircraft's electrical energy reserves. This includes portable and stationary charging systems that are designed to be connected to an aircraft as well as battery swapping programs. **NFPA 70**

3.2.9 *Energy Storage System (ESS), n*—Complete energy storage device consisting of one or more energy storage cells arranged into one or more packs, with ancillary subsystems for physical support and enclosure, thermal management, and electronic control. Typical energy storage cells include, but are not limited to, batteries or capacitors.

3.2.10 *FATO, n*—Final Approach and Takeoff area; a defined area over which the aircraft completes the final phase of the approach to a hover or a landing, and from which the aircraft initiates takeoff that has an unobstructed perimeter area that allows for safe maneuvering of the design aircraft in all modes of operation. The FATO elevation is the lowest elevation of the edge of the TLOF. The FATO may or may not need to be load bearing dependent upon the type of operations that are intended to be conducted.
